

Building a Sports Quiz Game in Python

A look into exception handling, text normalization, and scalable game logic

Presented by: Ankur Kashyap

Reg No: 26BCE10132

What the Project Does

- **Interactive CLI Concept:** A terminal-based trivia application built to test users on sports trivia across distinct paths like Cricket and Football.
- **User-Driven Choices:** Players self-select their favorite sport pathway, triggering customized question branches that adapt based on live input.
- **Smart Validation Goal:** Designed to handle human input dynamically, ensuring that strict formatting constraints don't break the user experience.

Handling Real-World Text Flaws

- **Preventing System Crashes:** Implemented try-except blocks to catch ValueError inputs when players type letters instead of numbers during selection screens.
- **String Normalization:** Leveraged functions like .strip() and .lower() to safely eliminate leading/trailing whitespace and remove case-sensitivity bugs.
- **Flexible spelling arrays:** Created inline array matching logic to allow common phonetic variations of names (e.g., 'Suryanshi' vs. 'Sooryavanshi') to prevent unfair penalties.

Refactoring for Scale & Growth

- **Decoupling Data:** Moving away from heavily nested if-else structures by migrating sports paths, quiz questions, and solutions into centralized dictionaries.
- **Dynamic Loops:** Replacing hardcoded sequential steps with clean iterative collection loops to allow infinite quiz growth without bloating code volume.
- **Future Upgrades:** Integrating score trackers, persistent high-score databases, and implementing fuzzy string matching for typos.
